An introduction to Bayesian modeling using R and JAGS

Instructors Kent Holsinger Xiaojing Wang

University of Connecticut

22 July 2015

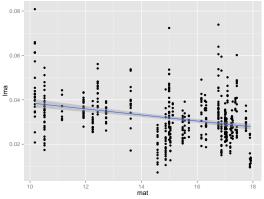

Overview of the Workshop

- Focus on using R and JAGS for Bayesian analysis
- Linear regression including mixed modeling Kent Holsinger
 - Simple linear regression
 - Multiple regression (including random effects)
- Multicollinearity Xiaojing Wang
 - Hierarchical independent prior distributions
 - Variable selection

Linear Regression

One of the most common statistical procedures in ecology and evolution. For example,

- ▶ Data on LMA from 535 individuals in the genus *Protea* (42 species, 48 sites, 142 unique site/species combinations)
- ▶ Data on mean annual temperature for each of those sites

Linear Regression

In R

```
> summarv(lm(lma ~ mat, data=tmp))
Call:
lm(formula = lma ~ mat, data = tmp)

Linear Regression

Remember basic assumptions of simple linear regression

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$

 $\epsilon_i \sim N(0, \sigma^2)$

Here's another way to write that

$$y_i \sim N(\mu_i, \sigma^2)$$

 $\mu_i = \beta_0 + \beta_1 x_i$

The second way of writing the model will be more convenient for us, so that's the approach we'll use.

Statistical Analysis

Statistical inference is the process of learning about the general characteristics of a population from a sample.

- ▶ Characteristics often expressed in terms of parameters θ .
- ▶ Measurements on the subset of members given by numerical values *Y*.
- ▶ Before the data are observed, both Y and θ are unknown.
- ▶ A probability model is assumed for observed data if we knew θ is the truth.
- ▶ What if we have prior information about θ ?

Bayesian Inference

Bayesian inference allows us to update prior beliefs with the observed data to quantify uncertainty about θ .

- ▶ Prior Distribution: $p(\theta)$
- ▶ Sampling Model (likelihood): $p(y \mid \theta)$
- Posterior Distribution

$$p(\theta \mid y) = \frac{p(y \mid \theta)p(\theta)}{p(y)}$$

► Calculating p(y) is typically very challenging. Use MCMC (implemented in JAGS) to estimate $p(\theta \mid y)$.

Metropolis-Hastings Algorithm

For θ_j

- Propose a new $\theta_j^* \sim q(\theta_j^{(t)}|\theta_j^t)$
- Calculate Metropolis-Hastings ratio

$$\alpha = \frac{p(Y|\theta_j^*)p(\theta_j^*)/q(\theta_j^*|\theta_j^{(t)})}{p(Y|\theta_j^{(t)})p(\theta_j^{(t)})/q(\theta_j^{(t)}|\theta_j^*)}$$

• if $\alpha < 1$ set

$$\theta_j^{(t+1)} = \begin{cases} \theta_j^* & \text{with probability } \alpha \\ \theta_j^{(t)} & \text{with probability } 1 - \alpha \end{cases}$$

If
$$\alpha > 1$$
 set $\theta_j^{(t+1)} = \theta_j^*$

- ▶ Repeat for j = 1, ..., J
- ▶ Repeat for t = 1, ..., T

Linear Regression - as a Bayesian

We start with the sampling model $p(y \mid \theta)$, where $\theta = (\beta_0, \beta_1, \sigma^2)'$,

$$y_i \sim N(\mu_i, \sigma^2),$$

 $\mu_i = \beta_0 + \beta_1 x_i,$

and x_i is the value of the covariate in individual i. Then we add prior distributions $p(\theta)$,

$$eta_0 \sim \mathsf{N}(0, au^{-1}),$$
 $eta_1 \sim \mathsf{N}(0, au^{-1}),$
 $\sigma^2 = rac{1}{ au_{resid}},$
 $au_{resid} \sim \mathsf{Gamma}(1, \phi)$

Linear Regression - in R+JAGS¹

Rescale all variables to mean of 0, standard deviation of 1

Multiple Linear Regression

Simple generalization of what we've already seen

$$y_i \sim N(\mu_i, \sigma^2),$$

 $\mu_i = \beta_0 + \sum_{k=1}^K \beta_k x_{ik},$

where x_{ik} is the value of the kth covariate in individual i. The priors are

$$\begin{array}{rcl} \beta_k & \sim & \mathsf{N}(0,\tau^{-1}), & k=0,\ldots,K \ , \\ \\ \sigma^2 & = & \frac{1}{\tau_{\mathit{resid}}} \ , \\ \\ \tau_{\mathit{resid}} & \sim & \mathsf{Gamma}(1,\phi). \end{array}$$

Problems with Multicollinearity

- Variables may appear to be unimportant (when they are).
- Coefficient estimates are unstable and hard to interpret (can estimate combinations of coefficients but not individual coefficients).

Alternative Bayesian solutions:

- Independent Prior Distributions
- Variable Selection

Hierarichal Model with Independent Priors

Hierarchical Model:

$$eta_j | \lambda_j, \sigma^2 \sim \mathsf{N}(0, \sigma^2/\lambda_j)$$
 $\lambda_j | \sigma^2 \sim \mathsf{Gamma}(1/2, 1/2)$ $1/\sigma^2 \sim \mathsf{Gamma}(
u_0/2,
u_0 \sigma_0^2/2)$

- Leads to nice conjugate updates for all full conditionals
- Easy to code in JAGS
- Allows each parameter to have own precision with mean 1

Cauchy Prior

First two equations imply that $\beta_j | \sigma^2 \sim \mathsf{Cauchy}(0, \sigma^2)$

$$p(\beta) = \frac{1}{\pi\sigma} \left(1 + \frac{\beta^2}{\sigma^2} \right)^{-1},$$

leading to a collapsed model

$$egin{align} Y|oldsymbol{eta}, \sigma^2 &\sim \mathsf{N}(Xoldsymbol{eta}, \sigma^2 I_n) \;, \ eta_j|\sigma^2 &\sim \mathsf{Cauchy}(0,\sigma^2) \;, \ 1/\sigma^2 &\sim \mathsf{Gamma}(
u_0/2,
u_0\sigma_0^2/2) \;. \ \end{aligned}$$

No nice full conditional for β_j .

Cauchy Prior

Independent N(0,1)

Stochastic Search Variable Selection

The Spike-and-Slab prior:

$$\beta_j \mid \gamma_j, c, \tau_j^{-1} \sim (1 - \gamma_j) \mathcal{N}(0, \tau_j^{-1}) + \gamma_j \mathcal{N}(0, \tau_j^{-1}c^2),$$

 $\gamma_j \mid \pi_j \sim Bernoulli(\pi_j).$

SPIKE&SLAB

- $\gamma_j = 0$: Variable not in the model;
- $\gamma_j = 1$: Variable in the model;
- ► Calibration of hyper-parameters c, τ_j^{-1} needed.

Inference for Variable Selection

- Highest posterior model (HPM): Select a model that has been visited most often.
- ▶ Median probability model (MPM): Select variables that appear at least in 50% of visited models.

Alternative spike and slab models

- Popular approach in genomic research;
- Variants:
 - Conjugate version:

$$\beta_j \mid \gamma_j, c, \tau_j^{-1} \sim (1 - \gamma_j) \mathcal{N}(0, \sigma^2 \tau_j^{-1}) + \gamma_j \mathcal{N}(0, \sigma^2 \tau_j^{-1} c^2).$$

▶ Replace the spike normal in Spike-and-Slab prior by Dirac, i.e.,

$$\beta_j \mid \gamma_j, \tau_j^{-1} \sim (1 - \gamma_j)\delta_0 + \gamma_j \mathcal{N}(0, \tau_j^{-1}).$$

Variable selection – Dirac + Normal

Model Selection

Selection of a single model has the following problems

- ▶ When the criteria suggest that several models are equally good, what should we report? Still pick only one model?
- ▶ What do we report for our uncertainty after selecting a model?

Typical analysis ignores model uncertainty!

Bayesian Model Choice

- ▶ Models for the variable selection problem are based on a subset of the x_1, \dots, x_p variables.
- ▶ Encode models with a vector $\gamma = (\gamma_1, \dots, \gamma_p)'$ where $\gamma_j \in \{0, 1\}$ is an indicator for whether variable x_j should be included in the model M_{γ} . Notice $\gamma_j = 0 \Leftrightarrow \beta_j = 0$.
- **Each** value of γ represents one of the 2^p models.
- ▶ Under model M_{γ} :

$$Y \mid oldsymbol{eta}, oldsymbol{\gamma}, au \sim \mathcal{N}(oldsymbol{X_{\gamma}}oldsymbol{eta_{\gamma}}, au^{-1} oldsymbol{\mathsf{I}})$$

where X_{γ} is the design matrix using the columns in X where $\gamma_j=1$ and β_{γ} is the subset of β that are non-zero.

Bayesian Model Averaging

Rather than use a single model, BMA uses all (or potentially a lot) models, but weights model predictions by their posterior probabilities (measure of how much each model is supported by the data).

Posterior model probabilities

$$P(M_j \mid Y) = \frac{P(Y \mid M_j)P(M_j)}{\sum_j P(Y \mid M_j)P(M_j)},$$

Marginal likelihod of a model is

$$P(Y \mid M_{\gamma}) = \int \int P(Y \mid \beta_{\gamma}, \tau) P(\beta_{\gamma} \mid \gamma, \tau) P(\tau \mid \gamma) d\beta_{\gamma} d\tau.$$

▶ Probability $\beta_j \neq 0$: $\sum_{M_i:\beta_i\neq 0} P(M_j \mid Y)$.

Bayesian Model Averaging (Continued)

Predictions

$$P(Y^{new} \mid Y) = \sum_{j} P(Y^{new} \mid Y, M_j) P(M_j \mid Y),$$

where

$$P(Y^{new} \mid Y, M_{\gamma}) = \int P(Y^{new} \mid Y, \beta_{\gamma}, \tau) P(\beta_{\gamma}, \tau \mid Y) d\beta_{\gamma} d\tau.$$
